Outline of Talk

- Introduction
 - The WA97 Experiment
-
- Inverse M_T Slopes
 - Particle Yields
 - Strangeness Enhancements
-
- Summary and Conclusions

Strangeness Enhancement

Gluon rich QGP:

Energy needed to produce $s\bar{s}$ pair
 $= 2m_s \sim 300 \text{ MeV}$.
 QGP temperature $\sim 200 \text{ MeV}$
 \therefore easy to produce $s\bar{s}$ pairs.

Many u and d quarks from initial ions so $u\bar{u}$ and $d\bar{d}$ suppressed by Pauli Blocking.

Aim of the WA97 experiment

The WA97 experiment studies the production of

strange and multistrange baryons and antibaryons

Λ , Ξ , Ω , with 1, 2, 3 units of strangeness respectively
(+ K_S^0)

\Rightarrow in **Pb–Pb** interactions at 158 A GeV/c beam momentum

\Rightarrow in **p–Pb** and **p–Be** interactions at the same beam momentum, for comparison

$$|y - y_{cm}| \leq 0.5$$

$$p_T \geq 0.3 \text{ GeV}/c \text{ for } \pi$$

$$\geq 0.7 \text{ GeV}/c \text{ for } \Omega$$

WA97 set-up

- Scintillator petals: most central ($\sim 40\%$) Pb-Pb collisions triggered;
- Mult. detectors: sample charged particles multiplicity ($2 < \eta < 4$);
- Silicon Telescope:** 7 pixel planes with $75 \times 500 \mu m^2$ pixel size
10 microstrip planes with $50 \mu m$ pitch;
- Pad chambers: improve momentum resolution of fast tracks;
- p-Pb trigger: events with at least two tracks in the telescope scintillators;

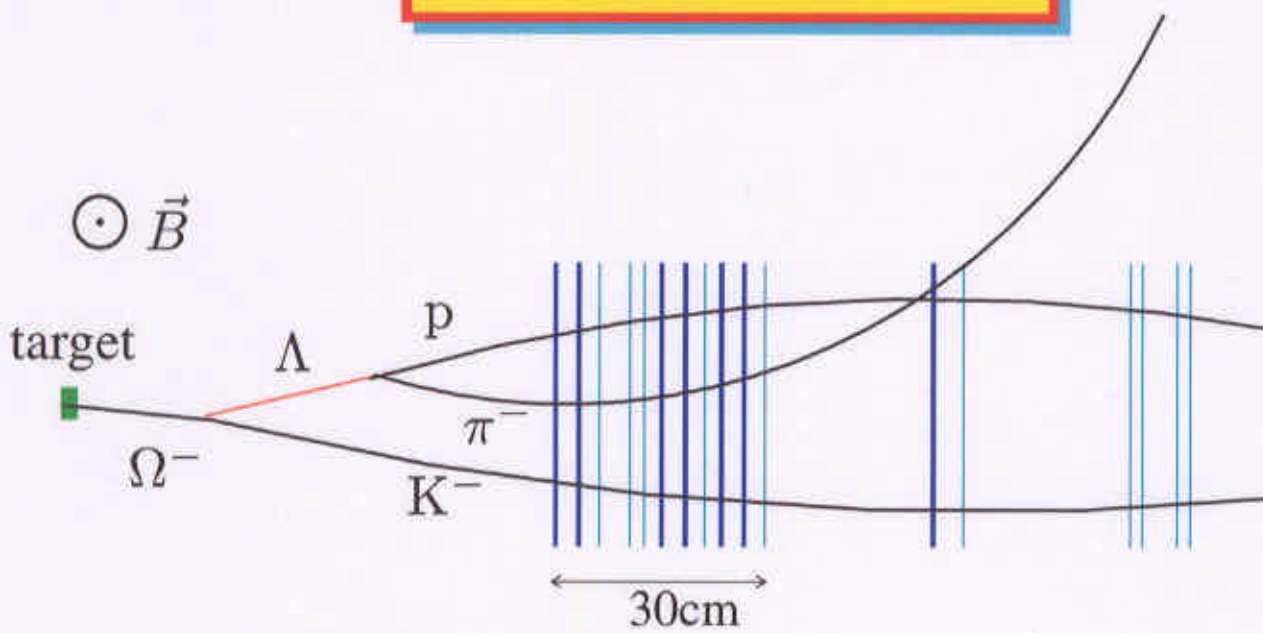

WA97 Pb-Pb event 1995

153 tracks through the Si Pixel Telescope

Decay reconstruction

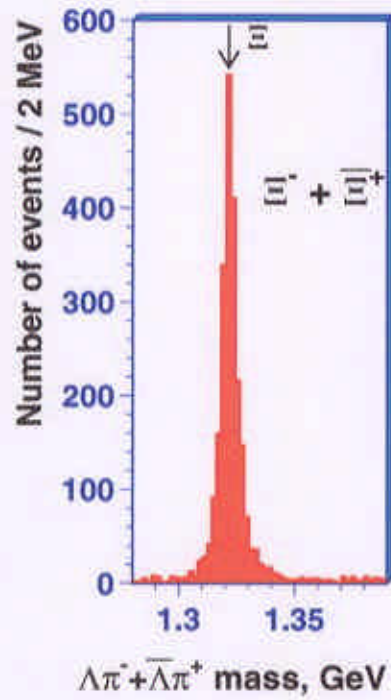

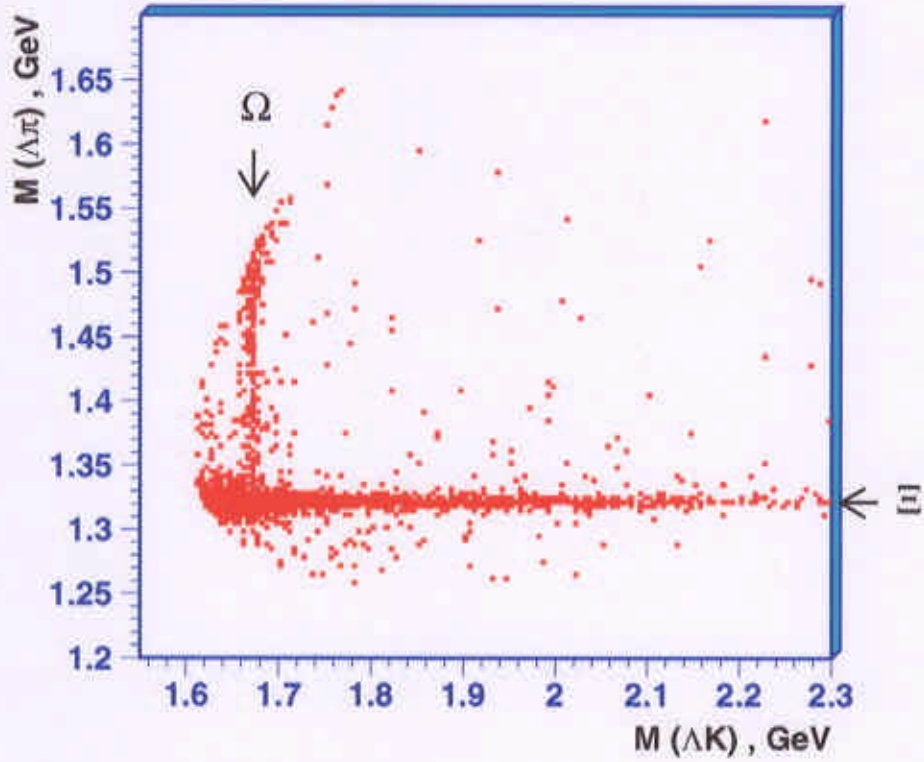

Strange baryons:

Multi-strange baryons:

Ξ and Ω in Pb-Pb

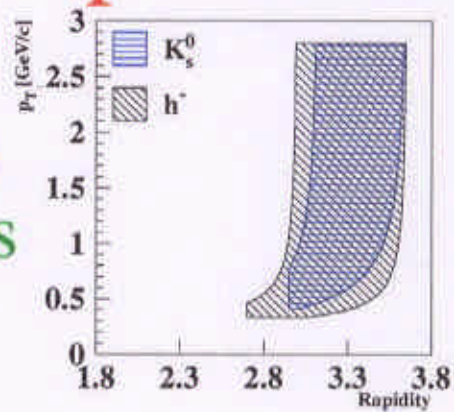

Acceptance Windows

Pb+Pb

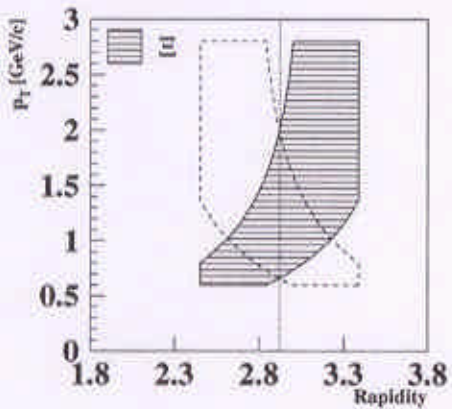

p+Pb/Be

h^-, K_s^0

$\Lambda, \bar{\Lambda}$

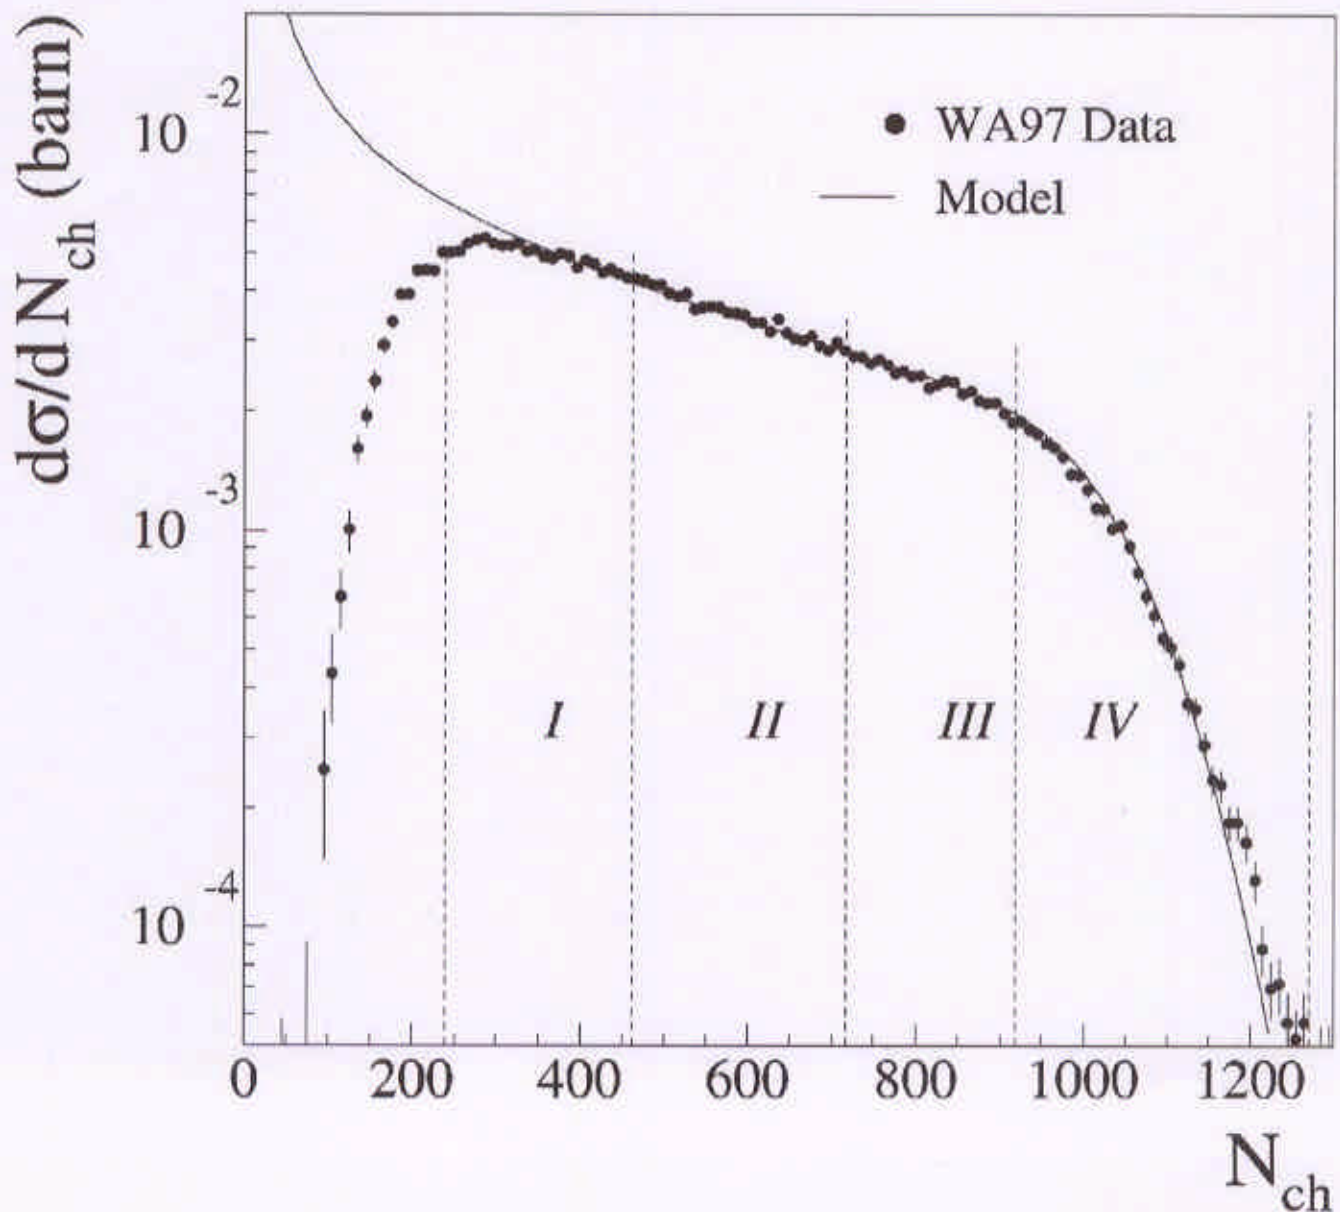

$\Xi^-, \bar{\Xi}^+$

$\Omega^-, \bar{\Omega}^+$

Centrality Measurement

- Full WA97 Pb-Pb sample $\sim 40\% \sigma_{\text{inel}}$
- Centrality measurement based on multiplicity in $2 < \eta < 4$ sampled by the MSD (silicon μ -strips)
- Data fitted with wounded nucleon model
 $\langle N_{\text{ch}} \rangle \propto \langle N_{\text{wound}} \rangle$
- WA97 data divided into 4 centrality classes

Results

We determine as a function of centrality:

- Inverse slope T of the m_T distributions, parametrized as:

$$\frac{dN(m_T, y)}{dm_T dy} = f(y) m_T \exp\left(-\frac{m_T}{T}\right)$$

$f(y)$ is assumed to be **constant** in the acceptance region of the experiment ($|y - y_{cm}| \leq 0.5$)

⇒ systematic error largest in p-Pb. Estimated by assuming

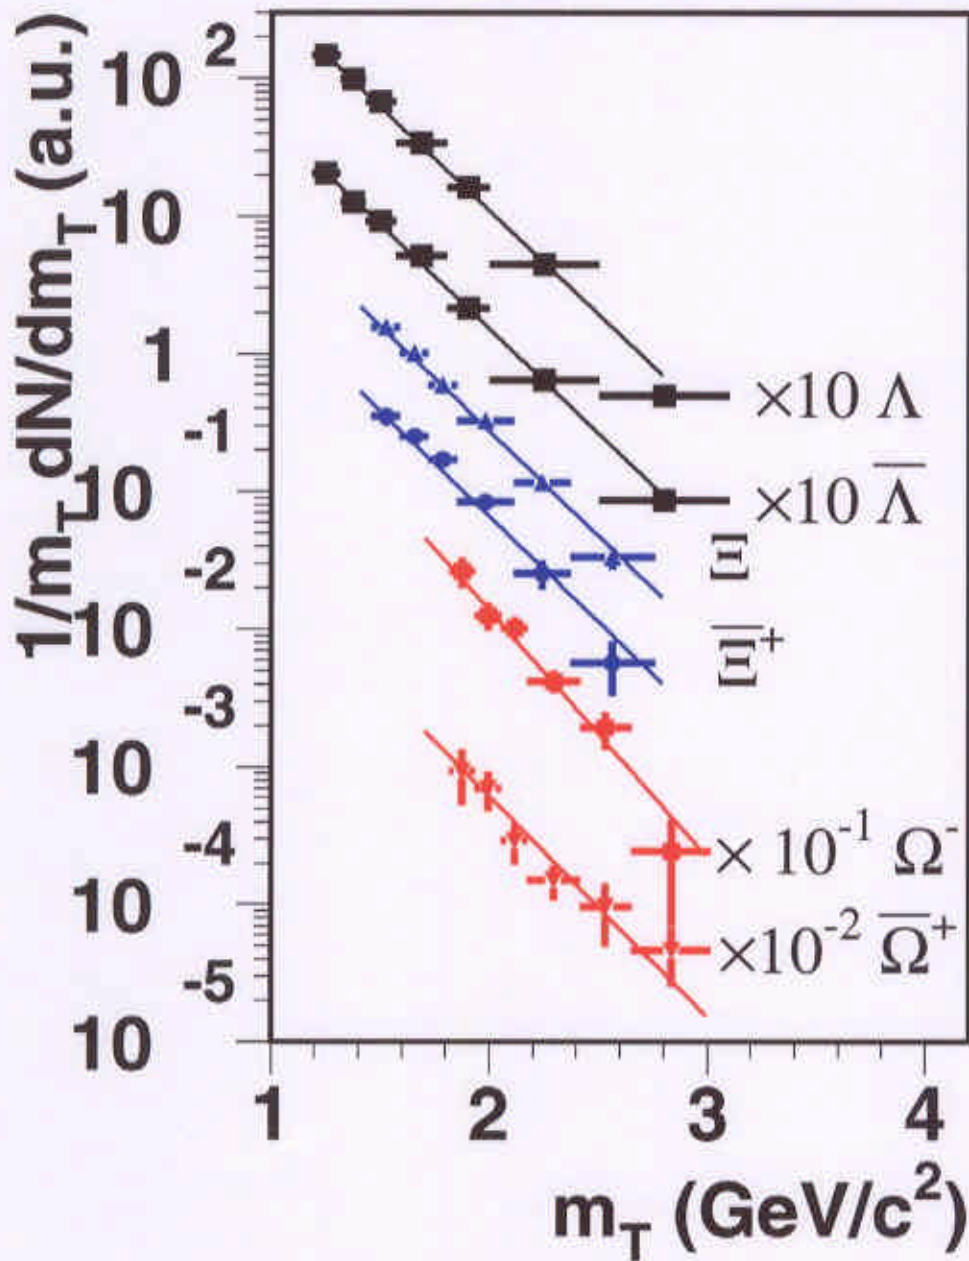

$f(y) \rightarrow$ **empirical fit** to published p-S and p-Au data:

	difference on the m_T slope	difference on the yields
Λ	10%	6%
$\bar{\Lambda}$	< 5%	< 5%

- Particle yields:

$$Y = \int_m^\infty dm_T \int_{y_{cm}-0.5}^{y_{cm}+0.5} dy \frac{dN(m_T, y)}{dm_T dy}$$

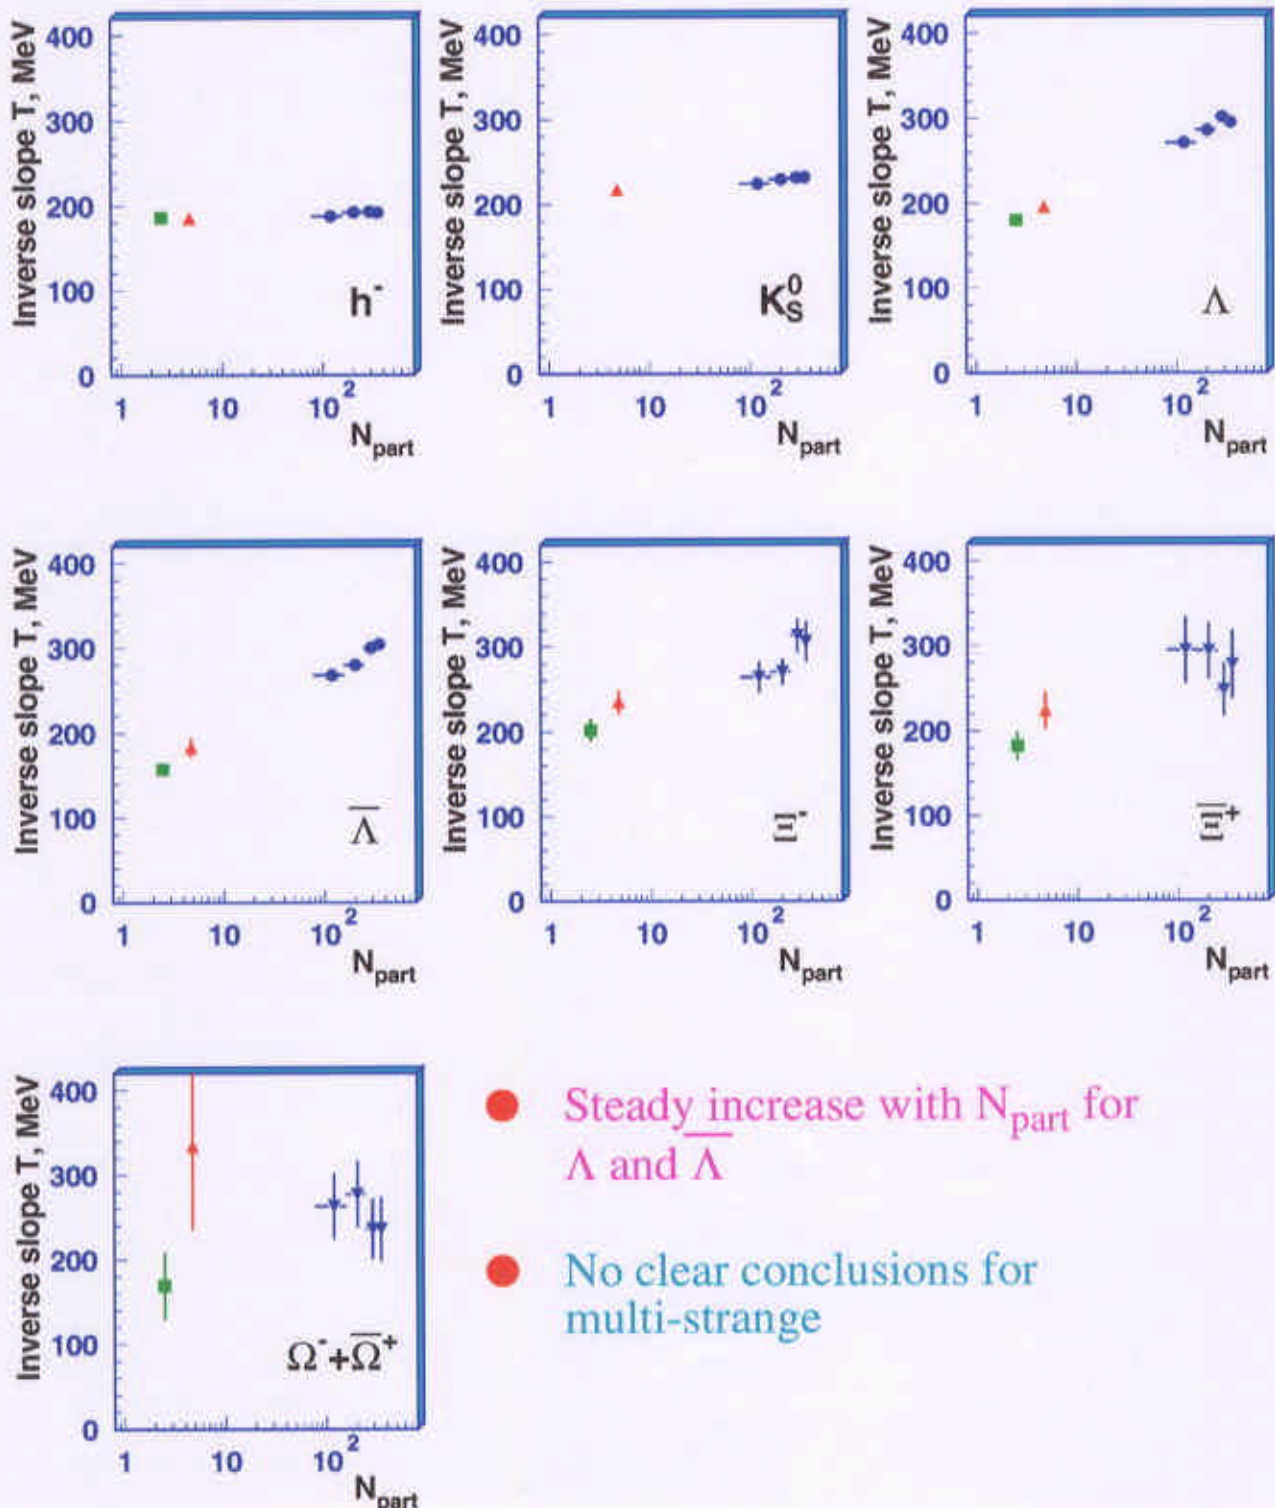

Hyperon transverse mass spectra in Pb–Pb

M_T Inverse Slopes vs N_{part}

● Fitted to $\frac{dN}{dm_T} \sim m_T \exp(-m_T/T)$

● p+Be, p+PB, 4 centrality classes in Pb+Pb

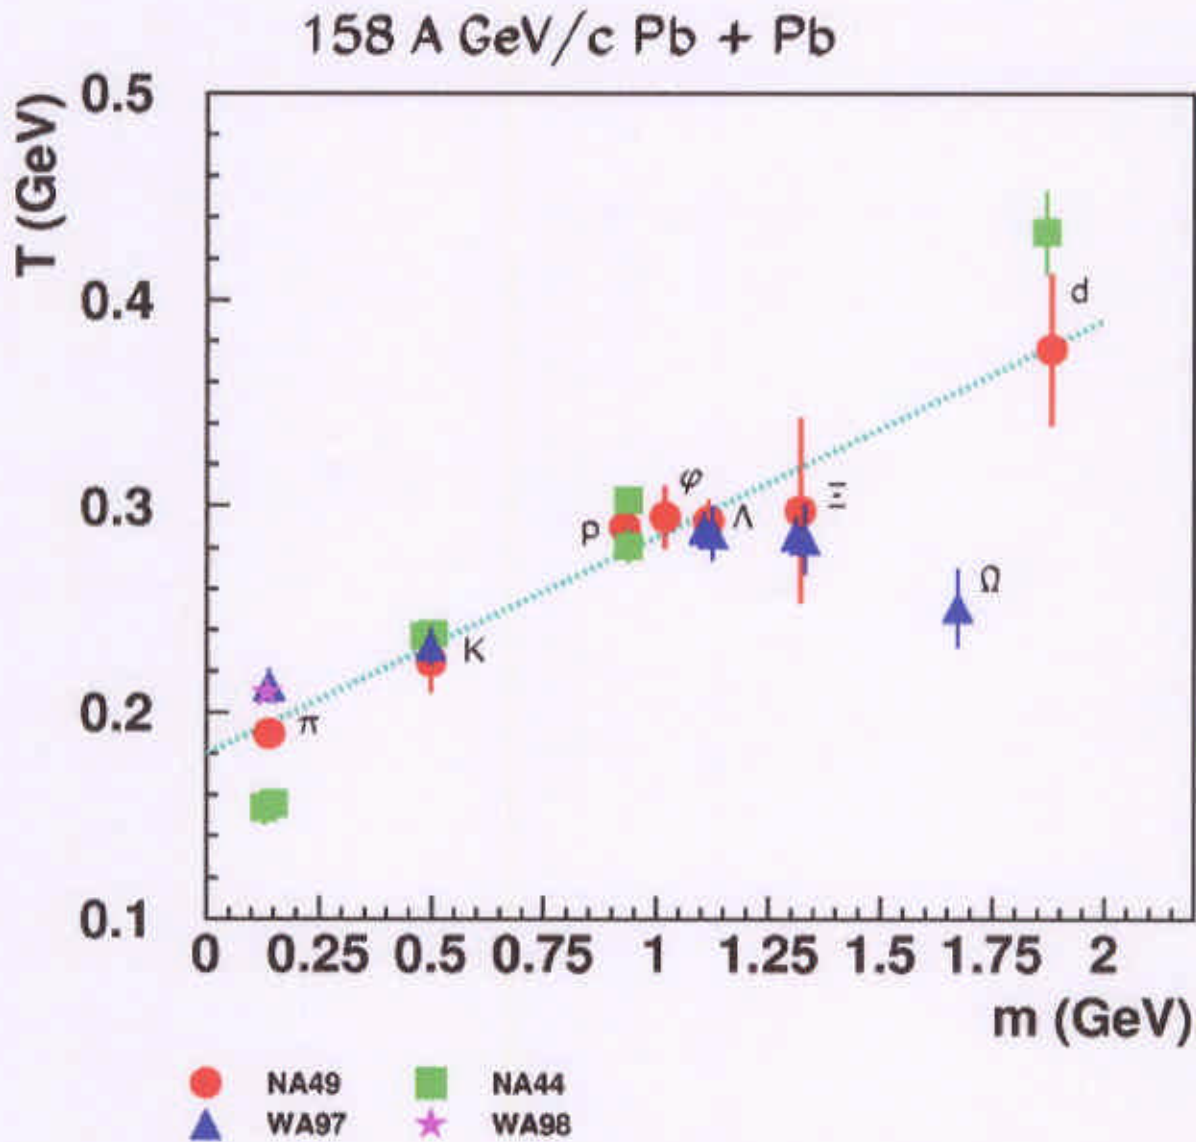

Centrality dependence of m_T spectra

h^- , K_S^0 slopes constant; Λ , $\bar{\Lambda}$ (and possibly Ξ^-) exhibit a slow but steady rise; Ξ^+ and $\Omega^- + \bar{\Omega}^+$ not a significant centrality dependence above $N_{wound} = 100$

(\Rightarrow more statistics coming)

Pb-Pb: m_T Inverse Slopes vs Particle Mass

- Linear increase with particle mass (global flow expectation)
- Ω inverse slope deviates

Particle Yields

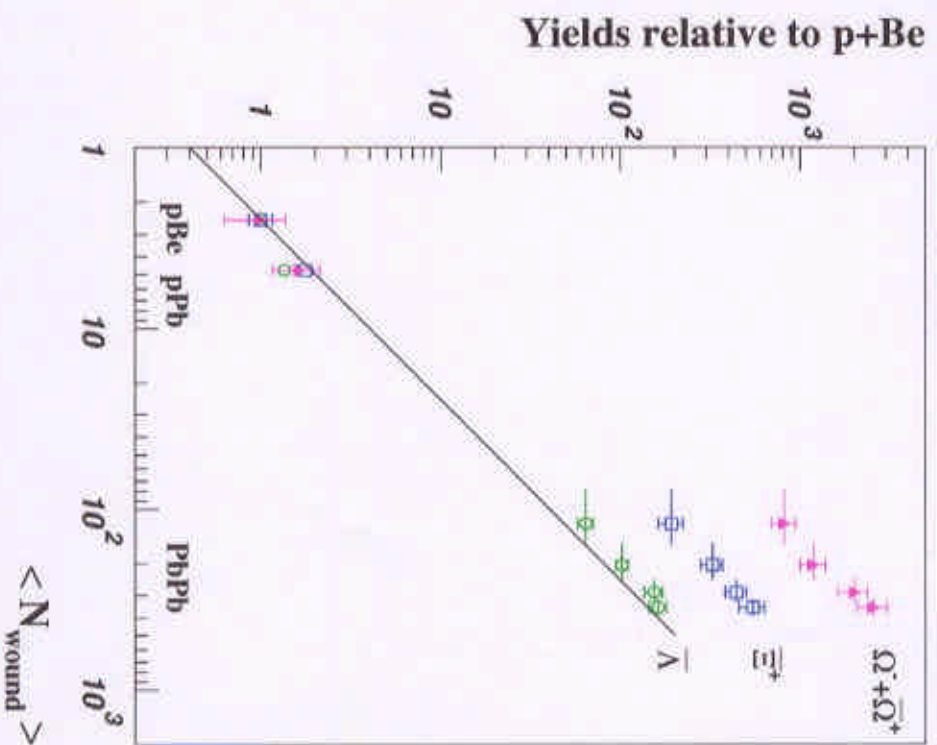

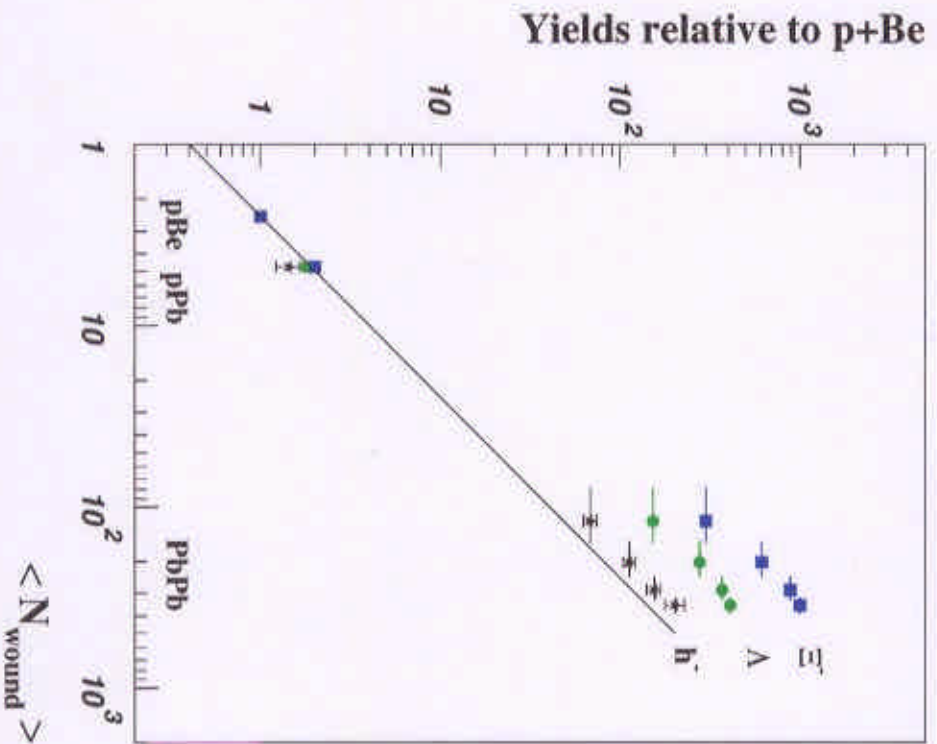

QGP prediction:

- strange (anti)baryon close to hadronic thermal and chemical equilibrium
- the (anti)hyperon enhancement is expected to increase with its strangeness content

$$Enhanc.(\Lambda) < Enhanc.(\Xi) < Enhanc.(\Omega)$$

(J.Rafelski and B. Müller, Phys.Rev.Lett.48 (1982)
1066)

Yields relative to p-Be

⇒ Pb-Pb yields enhanced with respect to p-Be; enhancements increase with strangeness.

⇒ Yields proportional to number of wounded nucleons in Pb-Pb centrality range.

$$Y = N_{\text{wound}}^{\beta}$$

Fit to Pb–Pb yields

Particle	β	χ^2	d.o.f
h^-	$0.97 \pm 0.07 \pm 0.04$	0.31	2
Λ	$0.94 \pm 0.08 \pm 0.04$	2.59	2
$\bar{\Lambda}$	$0.91 \pm 0.13 \pm 0.04$	0.62	2
Ξ^-	$1.14 \pm 0.08 \pm 0.05$	2.89	2
Ξ^+	$0.96 \pm 0.19 \pm 0.04$	0.02	2
$\Omega^- + \bar{\Omega}^+$	$1.06 \pm 0.18 \pm 0.05$	0.95	2

$\Rightarrow \beta \sim 1$ in Pb–Pb centrality range

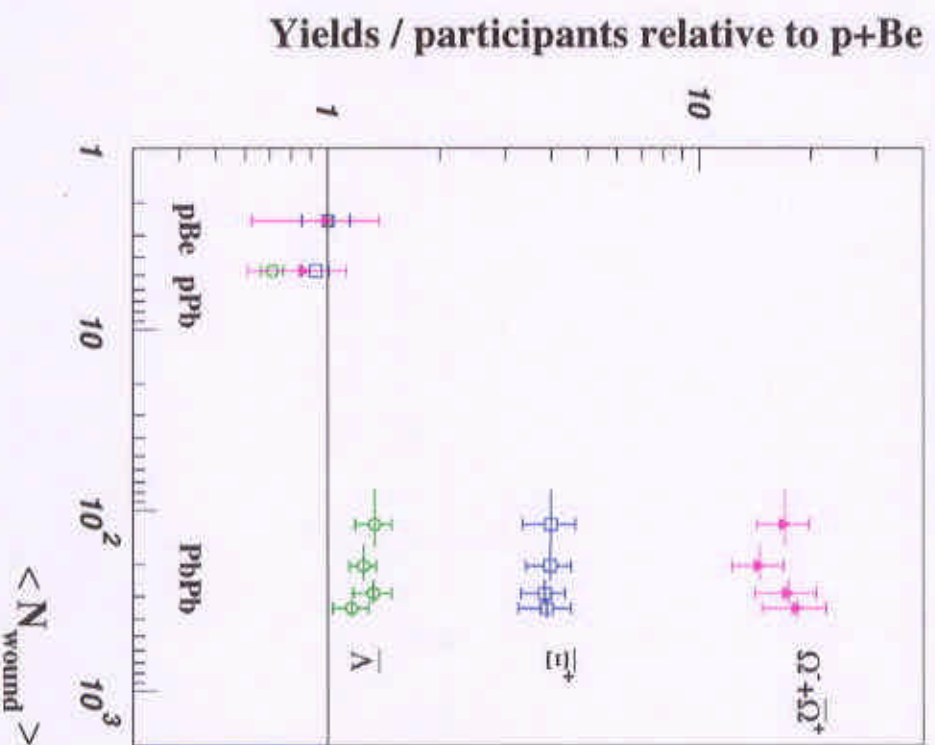

Question: β depending on particle species?

Fit both **Pb–Pb** AND **p–Be** yields

Particle	β	χ^2	d.o.f
h^-	$1.073 \pm 0.011 \pm 0.005$	1.07	3
Λ	$1.258 \pm 0.007 \pm 0.005$	21.1	3
$\bar{\Lambda}$	$1.051 \pm 0.012 \pm 0.005$	1.85	3
Ξ^-	$1.426 \pm 0.016 \pm 0.003$	15.8	3
Ξ^+	$1.291 \pm 0.036 \pm 0.003$	3.12	3
$\Omega^- + \bar{\Omega}^+$	$1.549 \pm 0.080 \pm 0.007$	7.44	3

\Rightarrow not favoured

Yield/participants relative to p-Be

⇒ Enhancements are saturated for $\langle N_{wound} \rangle > 100$

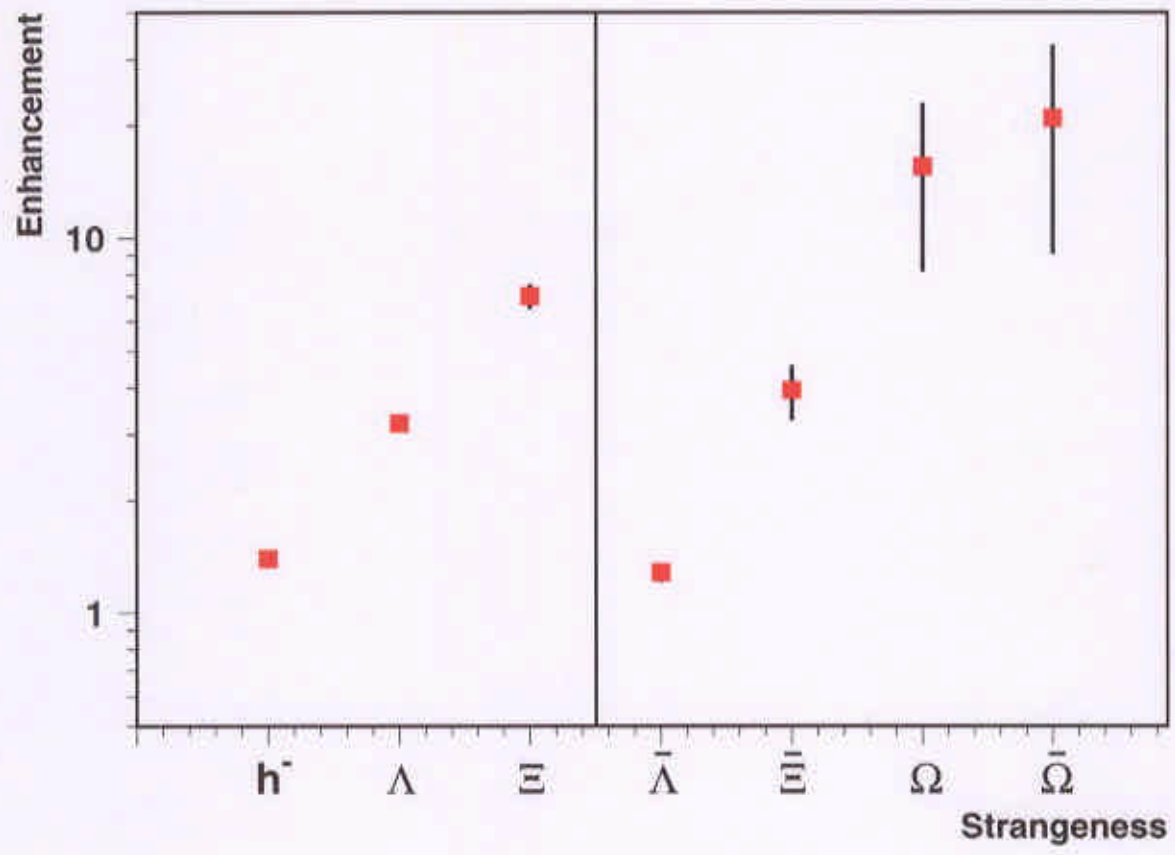

⇒ Enhancement is larger for particles of higher strangeness content

Enhancement relative to p-Be

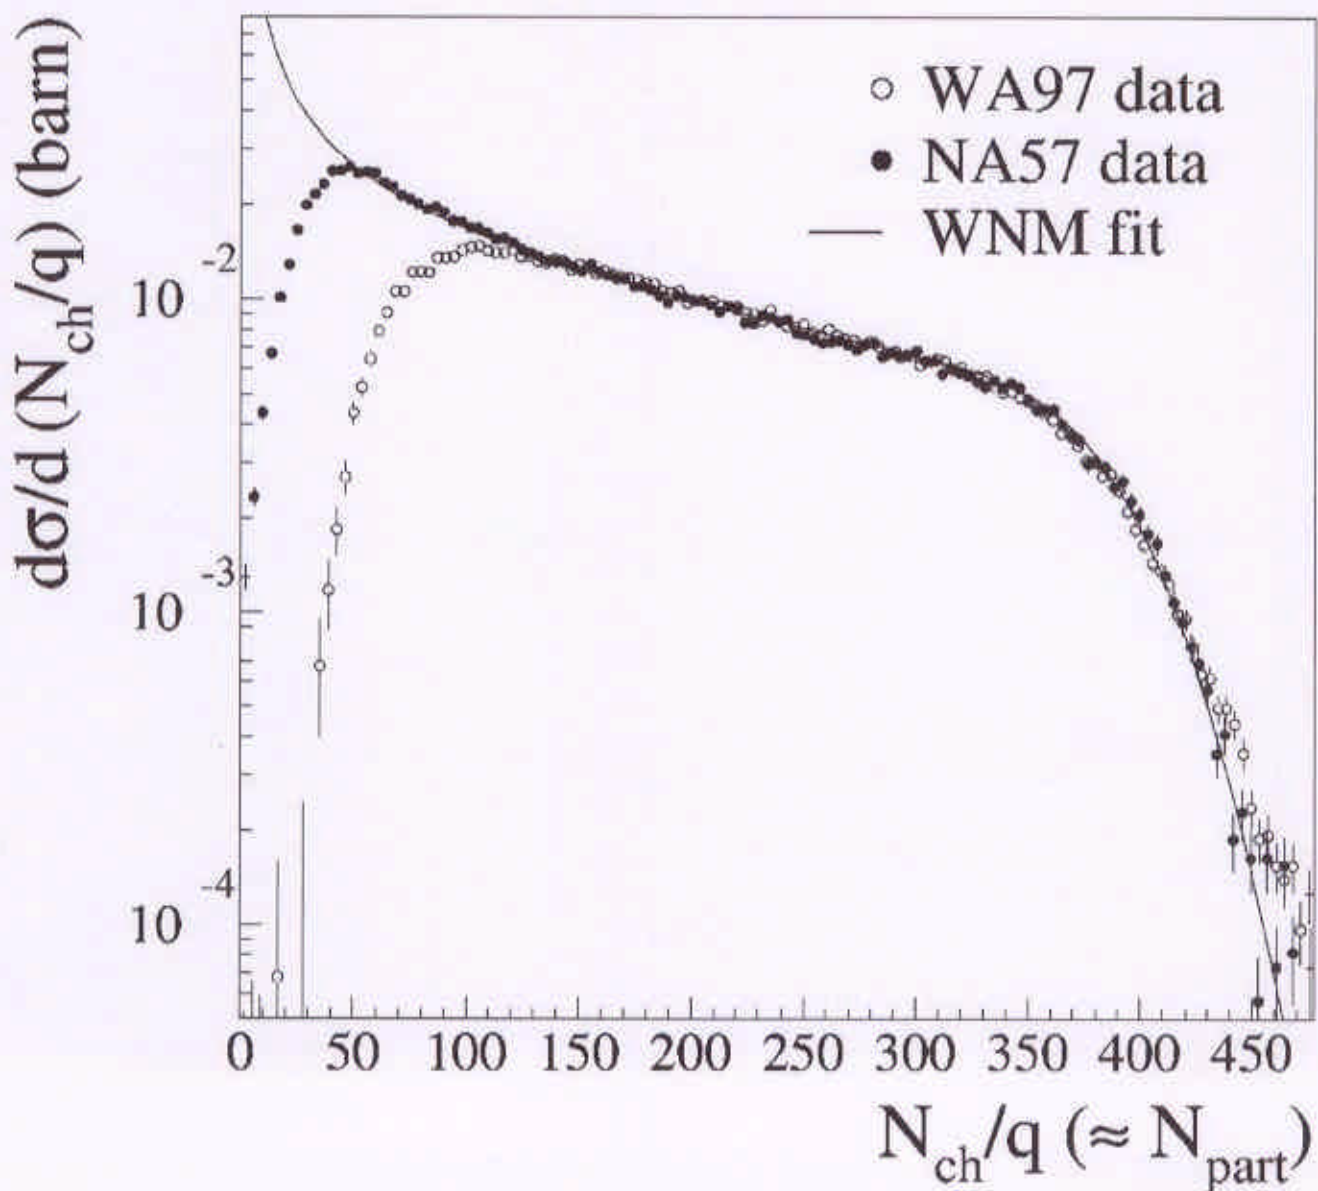

$$E = \left(\frac{\langle Yields \rangle}{\langle N_w \rangle} \right)_{Pb-Pb} / \left(\frac{\langle Yields \rangle}{\langle N_w \rangle} \right)_{p-Be}$$

$$E \sim 16 \text{ for } \Omega + \bar{\Omega}$$

NA57

- Apparatus similar to WA97 (different magnet)
- expect $\sim 2 \times$ WA97 statistics at 160 A GeV/c
- 230M events collected in 1998
(Pb-Pb, 160 A GeV/c, extended centrality range)

Summary & Conclusions

- Inverse m_T slopes constant with N_{wound} for negatives but increase with N_{wound} for Λ , $\bar{\Lambda}$.
- Strange particles enhanced in Pb-Pb interactions w.r.t. p-Be interactions. Strange particles not enhanced in p-Pb ints.
- Enhancement increases with strangeness content. Ω s enhanced by an order of magnitude.
- Mechanism responsible for the enhancement is already saturated at $N_{\text{wound}} \sim 100$.
- Results are compatible with Quark-Gluon Plasma formation in central Pb-Pb interactions.
- New data are coming from NA57 (extended centrality, lower beam energy)
